

HOSPITAL APPOINTMENT-NO SHOW REPORT

Introduction

This analysis examines hospital appointment attendance patterns using **111K appointment records**. The purpose of the analysis is to identify factors associated with missed appointments and provide recommendations that could help the hospital improve attendance and reduce the operational impact of no-shows.

Key Findings

The dashboard shows that **80% of appointments were attended, while 20% were no-shows**. Although the majority of patients attended their appointments, a 20% no-show rate represents a significant number of missed appointments and may contribute to wasted clinical capacity and longer waiting times for other patients.

Age appears to be an important factor. The **18–30 age group recorded the highest no-show rate at 25%**, followed by patients **under 18 at 22%** and those aged **31–45 at 21%**. The no-show rate was lower among patients aged **46–60 (18%)** and **over 60 (15%)**. This suggests that younger patients may require more targeted appointment reminders or engagement.

Waiting time also shows a clear pattern. **Same-day appointments had the lowest no-show rate at 5%**, while the rate increased to **24% for 1–7 days**, **30% for 8–14 days**, and approximately **33% for appointments waiting 15 days or longer**. This indicates that longer waiting periods may increase the likelihood of patients missing appointments.

The weekday analysis shows relatively similar no-show rates from Monday to Friday, while **Saturday has the highest rate at approximately 23%**. The neighbourhood analysis also shows considerable variation, with some neighbourhoods recording no-show rates as high as **100%**, although these extreme values may be influenced by very small numbers of appointments and should therefore be interpreted cautiously.

Recommendations

1. Introduce targeted reminders for longer waiting periods.

Patients whose appointments are scheduled more than one week in advance should receive additional SMS reminders or confirmation calls shortly before their appointment. This could help reduce the increase in no-shows associated with longer waiting times.

2. Develop targeted engagement for younger patients and high-risk areas.

The hospital should focus reminder campaigns on younger age groups and neighbourhoods with consistently high no-show rates. Appointment confirmations, SMS notifications, and patient education could be used to improve attendance.

Conclusion

Overall, the dashboard indicates that **waiting time, age, weekday, and neighbourhood are useful factors for understanding appointment no-shows**. Targeted reminders and patient engagement strategies could help the hospital reduce missed appointments and improve the efficiency of healthcare services.

One correction before you submit: your **Gender chart currently displays 15K and 8K**, which look like *counts of no-shows*, not percentages. I would rename that chart to “**No-Shows by Gender**” unless you change the visual to show actual no-show rates.
